

SOFTWARE, AFTER AGENTS

Stop renting screens *nobody opens.*

Every tool you rent is three things: your data, some rules, and a screen. The screen is the part you pay for. Temple keeps the data and the rules, and drops the screen.

• live demo • `temple-incredicorp-production.up.railway.app`

01

The work moved to
agents. The invoices didn't.

Six databases wearing six interfaces.

6 subscriptions · 6 permission models · 6 audit trails · 0 owned

Your tools are data, rules,
and a screen. You only
ever paid for the screen.

Databases wearing screens

- Project tracking, Linear and Jira
- Docs and wiki, Notion, Confluence, SharePoint
- CRM and large parts of ERP

These are databases wearing screens. Keep the data, drop the rent.

Worth paying for

- Capture, where a bot must attend, Fireflies
- External data and enrichment networks
- The rare human moment, rendered on demand

You buy capability, not a screen.

02

Keep the data. Keep the
rules. Drop the screen.

Where Temple sits in your organisation.

Rules agents cannot break.

The same pipeline serves the web shell and every agent. A viewer cannot transition, an agent cannot approve, and every change lands in the audit log.

One engine. Three shapes of work.

A blueprint is declarative data, not code: states, legal transitions, guards, invariants, role policy. The engine runs whatever shape you declare.

Flow

linear-like · state machine

Issues move through legal transitions only.
Guards block half-done work, invariants make bad states unreachable, policy says who may approve.

Pages

notion-like · typed databases

Databases hold pages with typed properties and a markdown body. Loosely structured, fully governed, every edit versioned.

Wiki

free-form · revisions + backlinks

The loosest shape: markdown pages in a tree.
An immutable revision on every save, [[backlinks]] extracted automatically.

A blueprint is a verified state machine.

This is `blueprints/flow.json`, exactly as deployed. An agent can start work and submit it for review. Only a human can approve, cancel or reopen.

“Verified” is a gate, not a sticker.

L1

Algebra

One initial state, every transition references real states.

L2

Reachability

No unreachable states, no dead ends, terminals stay terminal.

L3

Soundness

No path of legal moves can reach a state that violates an invariant.

L4

Property

200 randomised action sequences, invariants hold throughout.

```
$ npm run verify
```

```
PASS blueprint: flow      L1 algebra ok · L2 reachability ok · L3 soundness ok · L4 property ok
```

```
PASS blueprint: pages    L1 ok · L2 ok · L3 ok · L4 ok
```

```
PASS blueprint: wiki     L1 ok · L2 ok · L3 ok · L4 ok
```

A blueprint that fails any level does not load. Change the spec, the verifier re-proves it before the engine will run it.

PROOF

Built and deployed, not a concept.

The running product

- Three verified apps over one PostgreSQL
- Login, roles and settings, the only human chrome
- 16/16 engine tests green, 3/3 blueprints verified
- Live on Railway with the seeded demo workspace

.up.railway.app

AGENTS GET A SURFACE TOO

MCP Apps render the work inside Claude.

The Flow board as an MCP App: ask Claude to show the board and this renders inline, live from the engine. No tab switch, no second login, same permissions.

When a person does need a screen, it appears, then it leaves.

Governance you can see

- The record card shows only the actions this caller's role is allowed to take
- The audit trail underneath is the real append-only log: who moved what, from which state, when
- Rendered as an MCP App, on demand, inside the conversation

03

€90k a year becomes
€3k a month.

The stack versus the layer.

	THE SAAS STACK	TEMPLE
Cost model	Per seat, per tool, forever	✓ Build once, flat run-rate
Permissions	One model per vendor, six to govern	✓ One policy layer, enforced in the bouncer
Audit trail	Scattered, partial, vendor-shaped	✓ Append-only, every transition, one place
Agent access	n connectors over UI-shaped APIs	✓ Native: MCP is the front door
Workflow logic	Implicit in screens and habits	✓ Explicit state machines, verified L1-L4
Your data	In six vendor silos	✓ In your PostgreSQL
Exit cost	A migration project per tool	✓ Zero. It is already yours.

Renting compounds. Owning flattens.

A €90k/yr stack with ~10% yearly price-and-seat creep: crossover at month 18, €109k kept by month 36, steady-state under half the run-rate, and you own the asset.
Incredicorp

One lifecycle at a time, never a big bang.

01

Educate

Show which subscriptions are pure interface, and what owning the data layer changes.

02

Prioritise

Map one lifecycle to an explicit, verified blueprint. Fixed-fee assessment.

03

Build

Stand up the owned layer and MCP bounce. Migrate that one workflow off SaaS.

04

Run

Host, maintain, govern. Cancel the subscription it replaced. Repeat.

A new revenue line, built on existing motion.

LINE	CONS.	BASE	UP
Assessments	90k	150k	210k
Implementations	300k	525k	750k
Managed run	45k	90k	150k
Blueprint library	24k	48k	60k
Year 1	€459k	€813k	€1.17M

Illustrative. ~60% blended gross margin. Exit ARR into year two: 6 managed-run clients × €36k plus 8 blueprint packs × €6k = €264k.

WHY NOW

Datadog just proved the engine on stage.

On Anthropic's conference stage, Datadog's VP of Engineering, Sesh Nalla, presented Tempor: a machine tool where agents emit a verified state-machine spec instead of improvised code. Same first principle, reached independently: most software is control logic around a database. They built it as internal infrastructure. The productised, governed version for the mid-market is wide open.

They proved the engine

Declarative blueprints, a compiler outside the LLM, a multi-level verifier, hot-reload into a hardened runtime, running against production-scale workloads.

We own the wedge

GDPR-ready, audit-clean, sold one lifecycle at a time to organisations that will never build this themselves.

THE CLOSE

Break even by month 18. Then it is yours.

We never sell a vision we can't build. Temple is live today, one verified lifecycle at a time.
