

A working demo is not a shipped agent.

You can wire up an AI agent in an afternoon. Getting it to run reliably in front of real users, every time, while you sleep, is a different discipline. This book is that discipline.

It walks the entire gap between a prototype that works once and an agent you can trust in production: the architecture that holds up, the evaluations that prove it works, the deployment that survives its first incident, and the team and business that grow around it.

You will learn to design the harness that turns a clever prompt into a reliable system, decide when a capability is a tool, a skill, or a subagent, build an eval suite wired into CI, draw the trust boundary between what runs alone and what a human signs off, ship a managed agent, and find the durable advantage when everyone has the same models.

Written for engineers and engineering leaders building agents right now. Eighteen chapters, each ending with concrete Ship Notes you can act on the same day.

Marco Kotrotsos specializes in practical AI implementation, with 30 years in IT now focused entirely on AI deployment. He writes the Autocomplete newsletter for practitioners.
